This is an abstract.

### 1. Introduction

This is text [1].

### 2. Related Work

SMOTE-ENC [2]

### 3. Motivation

$C_{maj}$  set of majority class observations (most common class found in the target variable)

$C_{min}$  set of minority class observations (least common class found in the target variable)

### 4. Proposed Method

## 5. Methodology

This section describes how the evaluation of G-SMOTENC was performed. We describe the datasets used in the experiment, their source and preprocessing steps carried out in Section 5.1. We describe the resampling and classifications methods used for comparing the performance of G-SMOTENC with other relevant oversampling and undersampling methods in Section 5.2. The performance metrics used are defined in Section 5.3. Finally, the experimental procedure is described in Section 5.4.

### 5.1. Experimental Data

The datasets used in this experiment were extracted from the UC Irvine Machine Learning Repository. All of the datasets are publicly available and cover a range of different domains. The selection of datasets was done to ensure that all datasets are imbalanced and contained non-metric features (*i.e.*, whether ordinal, nominal or binary). These datasets will be used to show how the performance of different classifiers varies according to the used over/undersampling method.

At an initial stage, all datasets were preprocessed manually with minimal manipulations, to avoid the application of preprocessing methods beyond the scope of this paper. This step was conducted to remove features and/or observations with missing values and identifying the non-metric features. The second stage of our preprocessing was done systematically. The resulting datasets are shown in Table 1.

Table 1: Description of the datasets collected after data preprocessing. The sampling strategy is similar across datasets. Legend: (IR) Imbalance Ratio

Dataset	Metric	Non-Metric	Obs.	Min. Obs.	Maj. Obs.	IR	Classes

Heart Disease	5	5	740	22	357	16.23	5
Heart Disease (21)	5	5	735	17	357	21.00	5

The second part of the data preprocessing pipeline starts with the generation of artificially imbalanced datasets with different Imbalance Ratios (IR). For each original dataset, we create its more imbalanced versions at intervals of 10, while ensuring that  $|C_{min}| \geq 15$ . The sampling strategy was determined for class  $n \in \{1, \dots, n, \dots, m\}$  as a linear interpolation using  $|C_{maj}|$  and  $|C'_{min}| = \frac{|C_{maj}|}{IR}$ , as shown in equation 1.

$$|C'_n|^{imb} = \frac{\frac{|C_{maj}|}{IR} - |C_{maj}|}{|\{1, \dots, n, \dots, m\}| - 1} \cdot |C_n| + |C_{max}| \quad (1)$$

The new, artificially imbalanced dataset, is formed by randomly removing observations from each  $C_n$  such that  $C'_n \subseteq C_n, |C'_n| = |C_n|^{imb}$ . The artificially imbalanced datasets are marked with its imbalance ratio as a suffix in Table 1.

The datasets (both original and artificially imbalanced versions) are then filtered to ensure all datasets have a minimum of 500 observations. The remaining datasets whose number of observations is larger than 5000 are randomly sampled to match this number of observations. Afterwards, for each remaining dataset we remove all observations from target classes whose frequency is lower than 15 observations. Finally, the continuous and discrete features are scaled to the range  $[0, 1]$  to ensure a common range between all features.

## 5.2. Machine Learning Algorithms

The choice of classifiers used in the experimental procedure were based on their type (tree-based, nearest neighbors-based, linear model and ensemble-based), popularity and consistency in performance. We used Decision Tree (DT), a K-Nearest Neighbors (KNN) classifier, a Logistic Regression (LR) and a Random Forest (RF).

Given the lack of existing oversamplers that address imbalanced learning problems with mixed data types, the amount of benchmark methods used is also limited. We used the well known methods that are compatible with this type of datasets: SMOTENC, Random Undersampling (RUS) and Random Oversampling (ROS). Table 2 shows the hyperparameters used for the parameter search described in Section 5.4.

## 5.3. Performance Metrics

Although the typical performance metrics, *e.g.*, Overall Accuracy (OA), are intuitive to interpret, they are often inappropriate to measure a classifier's performance in an imbalanced learning context [CITATION]. For example, to estimate an event that occurs in 1% of the dataset, a constant classifier would obtain an OA of 0.99 and still be unusable. However, this metric is still reported in some of our results to maintain a metric that is easier to interpret.

More recent surveys have found the Geometric-mean ( $G\text{-mean} = \sqrt{Sensitivity \times Specificity}$ ), F1-score ( $F\text{-score} = 2 \times \frac{Precision \times Recall}{Precision + Recall}$ ),  $Sensitivity = \frac{TP}{FN + TP}$  and  $Specificity = \frac{TN}{TN + FP}$  to be commonly used performance metrics in imbalanced learning contexts [3]. These metrics are calculated as a function

Table 2: Hyperparameter definition for the classifiers and resamplers used in the experiment.

Classifier		
DT	min. samples split	2
	criterion	gini
	max depth	3, 6
LR	maximum iterations	10000
	multi-class	One-vs-All
	solver	saga
	penalty	None, L1, L2
KNN	# neighbors	3, 5
	weights	uniform
	metric	euclidean
RF	min. samples split	2
	# estimators	50, 100
	Max depth	3, 6
	criterion	gini
Resampler		
SMOTENC	# neighbors	3, 5
G-SMOTENC	# neighbors	3, 5
	deformation factor	0.0, 0.25, 0.5, 0.75, 1.0
	truncation factor	-1.0, -0.5, 0.0, 0.5, 1.0
	selection strategy	“combined”, “minority”, “majority”
RUS	replacement	False
ROS	(no applicable parameters)	

of the number of False/True Positives (FP and TP) and False/True Negatives (FN and TN), having  $Precision = \frac{TP}{TP+FP}$  and  $Recall = \frac{TP}{TP+FN}$ . This finding is consistent with other well-known recommendations on the usage of performance metrics [4]. This led us to adopt, along with OA, both F-score and G-mean as the main performance metrics for this study.

#### 5.4. Experimental Procedure

The experimental procedure was applied similarly to all combinations of resamplers, classifiers and hyperparameter combinations across all datasets. The evaluation of the models’ performance was tested using a 5-fold Cross Validation (CV) approach. The mean performance in the test set is calculated over the 5 folds and 3 different runs of the experimental procedure for each combination resampling/classifier hyperparameters. For each dataset, results of the hyperparameters that optimize the performance of a resampler/classifier are selected. These results were then used for analysis and are shown in Table 7 (see Appendix). Figure 1 shows a diagram of the experimental procedure described.

A CV run consists of a stratified partitioning (*i.e.*, each partition contains the same relative frequencies of target labels) of the dataset into five parts. A given resampler/classifier combination with a specific set of hyperparameters is fit and tested five times, using one of the partitions as a test set and the remaining ones as training set. The estimated performance consists of the average classification performance across the five different test sets.

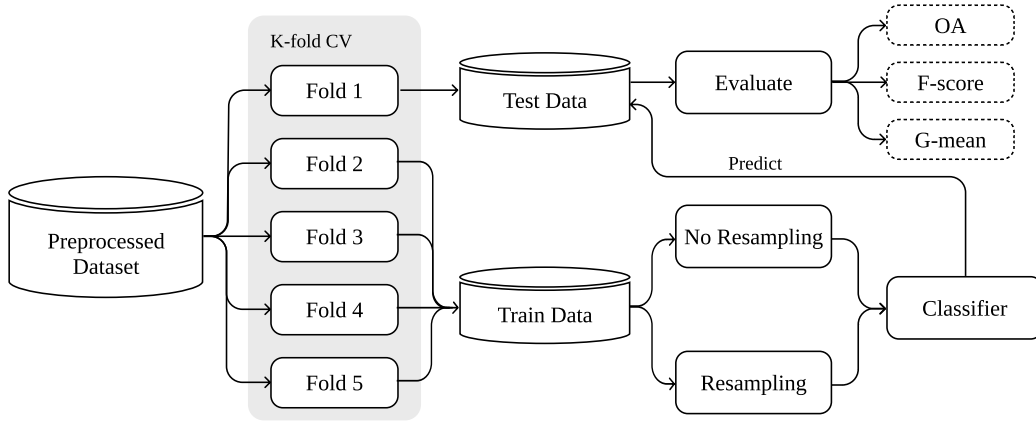

Figure 1: Experimental procedure used in this study.

## 5.5. Software Implementation

The algorithmic implementation of G-SMOTENC was written using the Python programming language and is available in the open-source package ML-Research [5], along with other utilities used to produce the experiment and outputs used in Section 6. In addition, the packages Scikit-Learn [6], Imbalanced-Learn [7] and Research-Learn were also used in the experimental procedure to get the implementations of the classifiers, benchmark over/undersamplers and run the experimental procedure. The Latex code, Python scripts (including data pulling and preprocessing, experiment setup and results’ analysis), as well as the datasets used are available in this GitHub repository.

## 6. Results and Discussion

In this section we present the experimental results. We focus on the comparison of classification performance using oversamplers whose generation mechanism is compatible with datasets containing both continuous and categorical features.

The analysis of our experimental results were developed in two stages: (1) analysis of mean ranking and absolute performance and (2) statistical analysis. In Section 6.3 we discuss the main insights extracted by analysing the results reported in Sections 6.1 and 6.2.

### 6.1. Results

Table 3 presents the mean rankings of cross validation scores across the different combinations of oversamplers, metrics and classifiers. These results were calculated by assigning a ranking score for each oversampler from 1 (best) to 4 (worst) for each dataset, metric and classifier, based on the results reported in Table 7 (see Appendix).

Table 3: Mean rankings over the different datasets, folds and runs used in the experiment.

## 6.2. Statistical Analysis

To conduct an appropriate statistical analysis in an experiment with multiple datasets, it is necessary to use methods that account for the multiple comparison problem. Based on the recommendations found in [8], we applied the Friedman test along with the Holm-Bonferroni test for a post-hoc analysis.

In Section 5.3 we explained that OA, although easily interpretable, is not an appropriate performance metric for imbalanced learning problems. Therefore, the statistical analysis was developed using the two imbalance-appropriate metrics used in the study: F-Score and G-Mean. The statistical analysis started with the assessment of a statistically significant difference in performance across resampling methods using a Friedman test [9]. The results of this test are shown in Table 5. The null hypothesis is rejected in all cases.

Table 5: Results for Friedman test. Statistical significance is tested at a level of  $\alpha = 0.05$ . The null hypothesis is that there is no difference in the classification outcome across resamplers.

Classifier	Metric	p-value	Significance
DT	F-Score	2.2e-10	True
DT	G-Mean	1.2e-10	True
KNN	F-Score	2.3e-09	True
KNN	G-Mean	9.4e-10	True
LR	F-Score	2.1e-07	True
LR	G-Mean	9.7e-11	True
RF	F-Score	8.5e-12	True
RF	G-Mean	2.0e-10	True

We performed a Holm-Bonferroni test to understand whether the difference in performance of G-SMOTENC is statistically significant to the remaining resampling methods. The results of this test are shown in Table 6. The null hypothesis was rejected in 27 out of 32 tests.

Table 6: Adjusted p-values using the Holm-Bonferroni test. Statistical significance is tested at a level of  $\alpha = 0.05$ . The null hypothesis is that the benchmark methods perform similarly compared to the control method (G-SMOTENC).
